hostname: login.galileo.cineca.it

early availability: 05/03/2018

start of production: 12/03/2018

system upgrade in production: 19/08/2019

Model: Lenovo NeXtScale
Architecture: Linux
Infiniband Cluster
Nodes: 1022
Processors: 2 x 18-cores
Intel Xeon E5-2697 v4 (Broadwell) at 2.30 GHz
Cores: 36 cores/node
RAM: 128 GB/node, 3.5 GB /core
Internal Network: Intel OmniPath, 100 Gb/s
Peak performance single node: 1.3 TFlop/s
Peak Performance: 1.5 PFlop /s

Accelerators: 60 nodes equipped with 1 nVidia K80 GPU
2 nodes equipped with 1 nVidia V100 GPU
Starting from 15th March 2021 Galileo will be turned off to make space for the new more performant infrastructure Galileo100.

The GALILEO supercomputer has been introduced first in January 2015 and in its first configuration, it has been available to the Italian public and industrial researchers until January 2018. It has been the national Tier-1 system for scientific research.

Starting from January 2018 GALILEO has been reconfigured with Intel Xeon E5-2697 v4 (Broadwell) nodes, inherited from MARCONI system. The cluster with this reconfiguration has opened for production in March of the same year.

Starting from August 2019 a new reconfiguration phase led to a new, upgraded environment, equipped with Intel Omni-Path internal network and increasing the number of compute nodes available to 1022 Intel Xeon E5-2697 v4 (Broadwell).

System Architecture

Compute Nodes: There are currently 1022 36-core compute nodes. Each one contains 2 18-cores Intel Xeon E5-2697 v4 (Broadwell) at 2.30 GHz. All the compute nodes have 128 GB of memory. Of these compute nodes, 60 are equipped with nVidia K80 GPU and two with nVidia V100.

Login and Service nodes: There are 8 Login & Viz nodes available (5 are academic nodes and 3 are for industrial users). There are 8 service nodes for I/O and cluster management.

All the nodes are interconnected through an Infiniband network, with OPA v10.6, capable of a maximum bandwidth of 100Gbit/s between each pair of nodes.

Accounting

For more information about accounting, please consult our dedicated section.

Budget Linearization policy

On GALILEO a linearization policy for the usage of project budgets has been defined and implemented. For each account, a monthly quota is defined as:

\[
\text{monthTotal} = \frac{\text{total_budget}}{\text{total_no_of_months}}
\]

Starting from the first day of each month, the collaborators of any account are allowed to use the quota at full priority. As long as the budget is consumed, the jobs submitted from the account will gradually lose priority, until the monthly budget (monthTotal) is fully consumed. At that moment, their jobs will still be considered for execution, but with a lower priority than the jobs from accounts that still have some monthly quota left.

This policy is similar to those already applied by other important HPC centers in Europe and worldwide. The goal is to improve the response time, giving users the opportunity of using the cpu hours assigned to their project in relation to their actual size (total amount of core-hours).

Disks and Filesystems

The storage organisation conforms to the CINECA infrastructure (see Section "Data storage and Filesystems") . In addition to the home directory ($HOME), for each user is defined a scratch area $CINECA_SCRATCH, a large disk for storing run time data and files. $WORK is defined for each active project on the system, reserved for all the collaborators of the project. This is a safe storage area to keep run time data for the whole life of the project.

<table>
<thead>
<tr>
<th></th>
<th>Total Dimension (TB)</th>
<th>Quota (GB)</th>
<th>Notes</th>

<td>1.000</td>
<td>permanent, project specific, local</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>extensions can be considered if needed (mailto: <a href="mailto:superc@cineca.it">superc@cineca.it</a>)</td>
</tr>
</tbody>
</table>

It is also available a temporary storage local on compute nodes generated when the job starts and accessible via environment variable $TMPDIR. For more details please see the dedicated section of UG2.5: Data storage and FileSystems. On Galileo the $TMPDIR local area has 49 GB of available space.

$DRES points to the shared repository where Data RESources are maintained. This is a data archive area available only on-request, shared with all CINECA HPC systems and among different projects.

$DRES is not mounted on the compute nodes. This means that you can't access it within a batch job: all data needed during the batch execution has to be moved on $WORK or $CINECA_SCRATCH before the run starts.
Since all the filesystems are based on gpfs (General Parallel File System), the usual unix command “quota” is not working. Use the local command “cindata” to query for disk usage and quota (“cindata -h” for help):

> cindata

**Modules environment**

The software modules are collected in different profiles and organized by functional category (compilers, libraries, tools, applications,…).

On GALILEO the profiles are of two types, “domain” type (chem, phys, lifesc,…) for the production activity and “programming” type (base and advanced) for compilation, debugging and profiling activities and that they can be loaded together.

“Base” profile is the default. It is automatically loaded after login and it contains basic modules for the programming activities (intel e gnu compilers, math libraries, profiling and debugging tools,…).

If you want to use a module placed under other profiles, for example an application module, you will have to load preventively the corresponding profile:

>module load profile/<profile name>
>module load autoload <module name>

For listing all profiles you have loaded you can use the following command:

>module list

In order to detect all profiles, categories and modules available on GALILEO the command “modmap” is available:

>modmap

With modmap you can see if the desired module is available and which profile you have to load to use it.

>modmap -m <module name>

**Production environment**

Since GALILEO is a general purpose system and it is used by several users at the same time, long production jobs must be submitted using a queuing system. This guarantees that access to the resources is as fair as possible.

Roughly speaking, there are two different modes to use an HPC system: Interactive and Batch. For a general discussion see the section ”Production Environment”.

**Interactive**

A **serial program** can be executed in the standard UNIX way:

> ./program

This is allowed only for **very short** runs, since the interactive environment set on the login nodes has a 10 minutes time limit: for longer runs please use the “batch” mode.

A parallel program can be executed interactively only by submitting an “Interactive” SLURM batch job, using the ”srun” command: the job is queued and scheduled as any other job, but when executed, the standard input, output, and error streams are connected to the terminal session from which srun was launched.

For example, to start an interactive session with the MPI program ”myprogram”, using one node and two processors, you can launch the command:

> srun -N 1 --ntasks-per-node=2 -A <account_name> --pty /bin/bash

SLURM will then schedule your job to start, and your shell will be unresponsive until free resources are allocated for you. If not specified, the default time limit for this kind of jobs is one hour.

When the shell returns a prompt inside the compute node, you can execute your program by typing:

> srun ./myprogram

or

> mpirun ./myprogram

The default SLURM MPI type has been set equal to PMI2.

SLURM automatically exports the environment variables you defined in the source shell, so that if you need to run your program ”myprogram” in a controlled environment (i.e. with specific library paths or options), you can prepare the environment in the login shell and be sure to find it again in the interactive shell on the compute node.
Batch

As usual, on systems using SLURM, you can submit a script script.x using the command:

```
> sbatch script.x
```

You can get a list of defined partitions with the command:

```
> sinfo
```

For more information and examples of job scripts, see section Batch Scheduler SLURM.

Submitting serial Batch jobs

The **gll_all_serial** partition is available with one core and a maximum walltime of 4 hours. It runs on two nodes and it is designed for pre/post-processing serial analysis, and for moving your data (via rsync, scp etc.) in case more than 10 minutes are required to complete the data transfer. In order to use this partition you have to specify the **SLURM flag “-p”**:

```
#SBATCH -p gll_all_serial
```

The **gll_all_serial** partition has a limit of 1 task per job and 4GB of memory per job. If you wish to ask for more than a core on a single job, remember to add on your jobscript the specific about the memory limit, since the default per core is 3.5GB and therefore your job won't enter because the required memory exceeds the partition limit.

**IMPORTANT FOR USERS OF THE PRE-UPGRADED VERSION OF GALILEO**: the old filesystems (such as `$CINECA_SCRATCH`) haven't been migrated to the upgraded cluster, but will remain available for a certain period of time (until the end of 2019) and visible only on specific nodes. You can access such nodes for transferring your data from the old environment to the new, by using the partition:

```
#SBATCH -p gll_all_transfer
```

with the limitations of one core and 24 hours per job. Inside the **gll_all_transfer** nodes, you will find your old scratch area at the mount point `/gpfs/scratch_old`.

Graphic session

If a graphic session is desired we recommend to use the tool “RCM”. See the corresponding session to know more about how to download and use RCM.

A complete reconfiguration of the RCM environment is in progress. This guide will be completed as soon as a final configuration will be implemented.

Submitting parallel Batch jobs

To run parallel batch jobs on GALILEO you need to specify the partition **gll_usr_prod**, or any other partition described in this user guide.

Users who need to run on GPU-equipped nodes need to specify the partition **gll_usr_gpuprod**.

If you do not specify the partition, your jobs will try to run on the default partition **bdw_all_serial**, meant for serial jobs, eventually failing if specific partition limits (maximum four tasks per job and maximum walltime of 4 hours) are violated.

The minimum number of cores you can request for a batch job is 1. The **maximum number of cores** that you can request is 2304 (64 nodes). It is also possible to request a **maximum walltime of 24 hours**. Defaults are as follows:

- If you do not specify the walltime (by means of the `#SBATCH --time` directive), a default value of 30 minutes will be assumed.
- If you do not specify the number of cores (by means of the `#SBATCH --nt` directive) a default value of 36 will be assumed.
- If you do not specify the amount of memory (as the value of the `#SBATCH --mem` DIRECTIVE), a default value of 3000MB will be assumed.
- The maximum memory per node is **118000MB**

A special QOS (**qos_special**) is also available for not-ordinary types of jobs, such as a walltime larger than 24 hours. Since it violates our standard policy, there are restrictions in its usage, and users who want to use it need to be enabled by the User Support staff. Please write to superc@cineca.it in case you think you need to use it. Your request will be evaluated and, if approved, you will be allowed to use the special QOS for a limited period of time.

Use of GPUs on GALILEO

The **gll_usr_gpuprod** partition is defined on 42 Broadwell nodes (18-cores Intel Xeon E5-2697 v4 @ 2.40GHz), each equipped with 1 nVidia K80 GPUs (seen as two K40 gpus). All users using an account with available budget can submit jobs on this partition and use GPU nodes on GALILEO.
The maximum number of nodes that can be required on gll_usr_gpuprod is 4 for a maximum walltime of 08:00:00 hours. The maximum memory is 118000 MB.

In regards of writing a SLURM jobscript, you need to request the GPU as "gres":

```
#SBATCH --partition=gll_usr_gpuprod
#SBATCH --gres=gpu:kepler:N  (N=1,2)
```

GALILEO is also equipped with two nodes with one nVIDIA Volta (V100) GPUs each, accessible for tests for a limited period of time. Please write to superc@cineca.it if you are interested to test the Volta GPUs, with a brief motivation for your request. Once your request is approved and you are enabled to use these resources (via the association to a special QOS "gll_qos_gpudev"), you can submit jobs to the Volta node with the following options:

```
#SBATCH --partition=gll_usr_gpudcv
#SBATCH --qos=gll_qos_gpudcv
#SBATCH --gres=gpu:volta:1
```

Users with reserved resources

Users of projects that require reserved resources (such as industrial users or users associated to an agreement that involves dedicated resources) will be associated to a QOS.

Using the specific QOS (i.e. specifying the QOS in the submission script), and specifying the partition gll_spc_prod, users associated to the allowed project will run their jobs on reserved nodes in the gll_spc_prod partition:

```
> #SBATCH --partition=gll_spc_prod
> #SBATCH --qos=<specific_qos>
```

Summary

In the following table, you can find all the main features and limits imposed on the SLURM partitions and QOS.

<table>
<thead>
<tr>
<th>SLURM partition</th>

</tbody>
</table>
Programming environment

The programming environment of GALILEO consists of a choice of compilers for the main scientific languages (Fortran, C and C++), debuggers to help users in finding bugs and errors in their codes, profilers to help with code optimization. In general, you must "load" also the correct environment for using programming tools like compilers, since "native" compilers are not available.

If you use a given set of compilers and libraries to create your executable, you will likely have to define the same "environment" when you want to run it. This is because, since by default linking is dynamic on Linux systems, at runtime the application will need the compiler shared libraries as well as other proprietary libraries. This means that you have to specify "module load" for compilers and libraries, both at compile time and at run time. If you prefer to minimize the number of needed modules at runtime, use static linking to compile the applications.

Compilers

You can check the complete list of available compilers on GALILEO with the command:

```bash
> module available
```

checking the "compilers" section.

In general, the available compilers are:

- **INTEL** (ifort, icc, icpc) : module load intel
- **PGI - Portland Group** (pgf77, pgf90, pgf95, pgfhp, pgcc, pgCC): module load pgi (profile/advanced)
- **GNU** (gcc, g77, g95): module load gnu

After loading the appropriate module, use the "man" command to get the complete list of the flags supported by the compiler, for example:

```bash
> module load intel
> man ifort
```

There are some flags that are common for all these compilers. Others are more specific. The most common are reported later for each compiler.

1. If you want to use a specific library or a particular include file, you have to give their paths, using the following options

   - `-I/path_include_files` specify the path of the include files
   - `-L/path_lib_files -l<xxx>` specify a library lib<xxx>.a in /path_lib_files

2. If you want to debug your code you have to turn off optimisation and turn on run time checkings: these flags are described in the following section.

   - `-02` or `-03` Higher optimisation levels

Other flags are available for specific compilers and are reported later.

**INTEL Compiler**

Intel family compiler suite is recommended on GALILEO, since the architecture is based on Intel processors and therefore using the Intel compilers may result in a significant improvement in performance and stability of your code. Initialize the environment with the module command:

```bash
> module load intel
```

The names of the Intel compilers are:

- `ifort`: Fortran77 and Fortran90 compiler
- `icc`: C compiler
- `icpc`: C++ compiler

The documentation can be obtained with the `man` command after loading the relevant module:

```bash
> man ifort
> man icc
```

Some miscellaneous flags are described in the following:

- `--extend_source` Extend over the 77 column F77's limit
- `--free / --fixed` Free/Fixed form for Fortran
- `-ip` Enables interprocedural optimization for single-file compilation
- `-ipo` Enables interprocedural optimization between files – whole program optimization

**PORTLAND Group (PGI)**

Initialize the environment with the module command:
The name of the PGI compilers are:

- `pgf77`: Fortran77 compiler
- `pgf90`: Fortran90 compiler
- `pgf95`: Fortran95 compiler
- `pghpf`: High Performance Fortran compiler
- `pgcc`: C compiler
- `pgCC`: C++ compiler

The documentation can be obtained with the `man` command after loading the relevant module:

```bash
> man pgf95
> man pgcc
```

Some miscellaneous flags are described in the following:

- `-Mextend` To extend over the 77 column F77's limit
- `-Mfree / -Mfixed` Free/Fixed form for Fortran
- `-fast` Chooses generally optimal flags for the target platform
- `-fastsse` Chooses generally optimal flags for a processor that supports SSE instructions

GNU compilers

The GNU compilers are always available but they are not the best optimizing compilers, especially for an Intel-based cluster like GALILEO. The default version is 4.8.5, you do not need to load the module for using it.

For a more recent version of the compiler, initialize the environment with the module command:

```bash
> module load gnu
```

The name of the GNU compilers are:

- `g77`: Fortran77 compiler
- `gfortran`: Fortran95 compiler
- `gcc`: C compiler
- `g++`: C++ compiler

The documentation can be obtained with the `man` command:

```bash
> man gfortran
> man gcc
```

Some miscellaneous flags are described in the following:

- `-ffixed-line-length-132` To extend over the 77 column F77's limit
- `-ffree-form / -ffixed-form` Free/Fixed form for Fortran

Debuggers and Profilers

If your code aborts at runtime, there may be a problem with it. In order to solve it, you can decide to analyze the core file (feature not available if the code is compiled with PGI) or to run your code using a debugger.

Compiler flags

In both cases, you need to enable compiler runtime checks, by putting specific flags during the compilation phase. In the following we describe those flags for the different Fortran compilers: if you are using the C or C++ compiler, please keep in mind that the flags may differ.

The following flags are generally available for all compilers and are mandatory for an easier debugging session:

```bash
-O0 Lower level of optimisation
-g Produce debugging information
```

Other flags are compiler-specific and are described in the following.

INTEL Fortran compiler

The following flags are useful (in addition to `-O0 -g`) for debugging your code:

```bash
-traceback (generate extra information to provide source file traceback at run time)
-fp-stack-check (enable checking for array subscript expressions)
-check bounds (enables checking for array subscript expressions)
-fpe0 (allows some control over floating-point exception handling at run-time)
```
PORTLAND Group (PGI) Compilers

The following flags are useful (in addition to "-O0 -g") for debugging your code:

- C                     Add array bounds checking
- Ktrap=ovf,divz,inv    Controls the behavior of the processor when exceptions occur:
                       FP overflow, divide by zero, invalid operands

GNU Fortran compilers

The following flags are useful (in addition to "-O0 -g") for debugging your code:

- Wall             Enables warnings pertaining to usage that should be avoided
- fbounds-check    Checks for array subscripts.

In the following we report informations about some ways to debug your codes:

PGI: pgdbg (serial/parallel debugger)

pgdbg is the Portland Group Inc. symbolic source-level debugger for F77, F90, C, C++ and assembly language programs. It is capable of debugging applications that exhibit various levels of parallelism, including:

- Single-thread, serial applications
- Multi-threaded applications
- Distributed MPI applications
- Any combination of the above

There are two forms of the command used to invoke pgdbg. The first is used when debugging non-MPI applications, the second form, using mpirun, is used when debugging MPI applications:

> pgdbg [options] ./myexec [args]
> mpirun [options] -dbg=pgdbg ./myexec [args]

More details in the on line documentation, using the "man pgdbg" command after loading the module.

To use this debugger, you should compile your code with one of the pgi compilers and the debugging command-line options described above, then you run your executable inside the "pgdbg" environment:

> module load profile/advanced
> module load pgi
> pgf90 -O0 -g -C -Ktrap=ovf,divz,inv -o myexec myprog.f90
> pgdbg ./myexec

By default, pgdbg presents a graphical user interface (GUI). A command-line interface is also provided through the "-text" option.

GNU: gdb (serial debugger)

GDB is the GNU Project debugger and allows you to see what is going on 'inside' your program while it executes -- or what the program was doing at the moment it crashed.

GDB can do four main kinds of things (plus other things in support of these) to help you catch bugs in the act:

- Start your program, specifying anything that might affect its behavior.
- Make your program stop on specified conditions.
- Examine what has happened, when your program has stopped.
- Change things in your program, so you can experiment with correcting the effects of one bug and go on to learn about another.

More details in the online documentation, using the "man gdb" command.

To use this debugger, you should compile your code with one of the gnu compilers and the debugging command-line options described above, then you run your executable inside the "gdb" environment:

> module load gnu
> gfortran -O0 -g -Wall -fbounds-check -o myexec myprog.f90
> gdb ./myexec

Core file analysis

In order to understand what problem was affecting your code, you can also try a "Core file" analysis. Since core files are usually quite large, be sure to work in the /scratch area.

There are several steps to follow:

1. Increase the limit for possible core dumping
If you are using Intel compilers, set to TRUE the `decfort_dump_flag` environment variable.

```bash
export decfort_dump_flag=TRUE  
```

1. Compile your code with the debug flags described above.
2. Run your code and create the core file.
3. Analyze the core file using different tools depending on the original compiler.

### INTEL compilers

```bash
module load intel
ifort -O0 -g -traceback -fp-stack-check -check bounds -fpe0 -o myexec prog.f90
ulimit -c unlimited
export decfort_dump_flag=TRUE
./myexec
```

### PGI compilers

```bash
module load profile/advanced
module load pgi
pgf90 -O0 -g -C -Ktrap=ovf,divz,inv -o myexec myprog.f90
ulimit -c unlimited
./myexec
```

### GNU Compilers

```bash
module load gnu
gfortran -O0 -g -Wall -fbounds-check -o myexec prog.f90
ulimit -c unlimited
./myexec
```

### VALGRIND

Valgrind is a framework for building dynamic analysis tools. There are Valgrind tools that can automatically detect many memory management and threading bugs, and profile your programs in detail. The Valgrind distribution currently includes six production-quality tools: a memory error detector, two thread error detectors, a cache and branch-prediction profiler, a call-graph generating cache profiler, and a heap profiler.

Valgrind is Open Source / Free Software, and is freely available under the GNU General Public License, version 2.

To analyse a serial application:

1. Load Valgrind module --> module load valgrind
2. Load module for the compiler and compile your code with the compiler you prefer (Use `-O0 -g` flags)
3. Run the executable under Valgrind.

   If you normally run your program like this:
   ```bash
   myprog arg1 arg2
   ```

   Use this command line:
   ```bash
   valgrind (valgrind-options) myprog arg1 arg2
   ```

   Memcheck is the default tool. You can add the `--leak-check` option that turns on the detailed memory leak detector. Your program will run much slower than normal, and use a lot more memory. Memcheck will issue messages about memory errors and leaks that it detects.

To analyse a parallel application:

1. Load Valgrind module --> module load valgrind
2. Load modules for compiler and openmpi libraries (at present only available for intel and gnu)
3. Compile your code with the `"-O0 -g"` flags both at compiling and linking time
4. Run the executable under Valgrind (both in interactive than in batch mode)
mpirun -np 4 valgrind (valgrind-options) myprog arg1 arg2

Totalview
Totalview is a parallel debugger with a practical GUI that assist users to debug their parallel code. It has functionalities like stopping and reprising a code mid-run, setting breakpoints, checking the value of variables anytime, browse between the different tasks and threads to see the different behaviours, memory check functions and so on. For information about how to run the debugger (by connecting the compute nodes to your display via RCM), type the command:

> module help totalview

Scalasca
Scalasca is a tool for profiling parallel scientific and engineering applications that make use of MPI and OpenMP. Details how to use scalasca in http://www.scalasca.org/software/scalasca-2.x/documentation.html

Profilers (gprof)
In software engineering, profiling is the investigation of a program's behaviour using information gathered as the program executes. The usual purpose of this analysis is to determine which sections of a program to optimize - to increase its overall speed, decrease its memory requirement or sometimes both.

A (code) profiler is a performance analysis tool that, most commonly, measures only the frequency and duration of function calls, but there are other specific types of profilers (e.g. memory profilers) in addition to more comprehensive profilers, capable of gathering extensive performance data.

gprof
The GNU profiler gprof is a useful tool for measuring the performance of a program. It records the number of calls to each function and the amount of time spent there, on a per-function basis. Functions which consume a large fraction of the run-time can be identified easily from the output of gprof. Efforts to speed up a program should concentrate first on those functions which dominate the total run-time.

gprof uses data collected by the -pg compiler flag to construct a text display of the functions within your application (call tree and CPU time spent in every subroutine). It also provides quick access to the profiled data, which let you identify the functions that are the most CPU-intensive. The text display also lets you manipulate the display in order to focus on the application's critical areas.

Usage:

> gfortran -pg -O3 -o myexec myprog.f90
> ./myexec
> ls -ltr

....... 
-rw-r--r-- 1 aer0 cineca-staff  506 Apr  6 15:33 gmon.out
> gprof myexec gmon.out

It is also possible to profile at code line-level (see "man gprof" for other options). In this case you must use also the "-g" flag at compilation time:

> gfortran -pg -g -O3 -o myexec myprog.f90
> ./myexec
> ls -ltr

....... 
-rw-r--r-- 1 aer0 cineca-staff  506 Apr  6 15:33 gmon.out
> gprof --annotated-source myexec gmon.out

It is possible to profile MPI programs. In this case, the environment variable GMON_OUT_PREFIX must be defined in order to allow to each task to write a different statistical file. Setting

export GMON_OUT_PREFIX=<name>

once the run is finished each task will create a file with its process ID (PID) extension <name>.$PID

If the environmental variable is not set every task will write the same gmon.out file.

Scientific libraries (MKL)

MKL
The Intel Math Kernel Library (Intel MKL) enables improving performance of scientific, engineering, and financial software that solves large computational problems. Intel MKL provides a set of linear algebra routines, fast Fourier transforms, as well as vectorized math and random number generation functions, all optimized for the latest Intel processors, including processors with multiple cores.

Intel MKL is thread-safe and extensively threaded using the OpenMP technology.

documentation can be found by loading the mkl module and searching in the directory:

$(MKLROOT)/../Documentation/en_US/mkl
To use the MKL in your code you to load the module, then to define includes and libraries at compile and linking time:

```bash
> module load mkl
> icc -I$MKL_INC -L$MKL_LIB -lmkl_intel_lp64 -lmkl_core -lmkl_sequential
```

For more informations please refer to the documentation.

**Parallel programming**

The parallel programming on Galileo is based on IntelMPI and OpenMPI versions of MPI. The libraries and special wrappers to compile and link the personal programs are contained in several modules, one for each supported suite of compilers.

These command names refer to wrappers around the actual compilers, they behave differently depending on the module you have loaded.

**IntelMPI**

IntelMPI in GALILEO is recommended since the architecture is based on Intel processors.

To load IntelMPI on GALILEO, check the module versions available with the “module avail” command, then load the relevant module. After you have loaded the Intelmpi module

```bash
> mpiifort -o myexec myprof.f90 (uses the ifort compiler)
```

For more option of the compiler, please see

```bash
> man mpiifort
```

The three main parallel-MPI commands for compilation with OpenMPI are:

- mpiifort (Fortran90/77)
- mpiiccc (C)
- mpiicpc (C++)

**OpenMPI**

On GALILEO, “gnu” versions of OpenMPI are available. After you have load the openmpi module (check the available version with the “module avail” command):

```bash
> mpif90 -o myexec myprof.f90 (uses the gfortran compiler)
```

The four main parallel-MPI commands for compilation with OpenMPI are:

- mpif90 (Fortran90)
- mpif77 (Fortran77)
- mpicc (C)
- mpiCC (C++)

In all cases the parallel applications have to be executed with the recommended command:

```bash
> srun ./myexec
```

There are limitations to running parallel programs in the login shell. You should use the “Interactive SLURM” mode, as described in the “Interactive” section, previously on this page.
